

# Patch-Based Texture Synthesis in 2D and 3D

Presented by Junwen Wu

CSE291-J

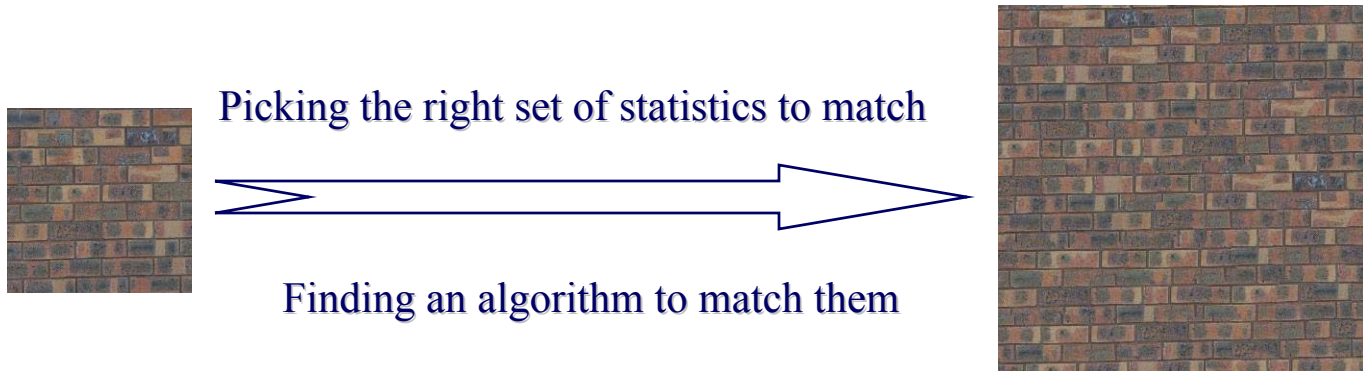

Feb. 27, 2003

# Introduction to Texture Synthesis

- Problem Description

Given: an input texture sample image  $I_{in}$

Target: an unlimited amount of image data  $I_{out}$ ,  
which is perceived by the human observer as the  
same texture

# Introduction to Texture Synthesis

- Two classes of textures

Stochastic Texture *V.S.* Structured Texture

- Histogram matching
- Conditional distribution preserving under multi-scale
- Patch pasting
- Pixel-wise non-parametric sampling

- Pixel-wise non-parametric sampling

Greedy strategy, Slow

Patch-based Texture Synthesis

# Patch-based Texture Synthesis in Images

- Alexei A. Efros, William T. Freeman, *Image quilting for Texture Synthesis and Transfer*, SIGGRAPH 2001  
(Image Quilting)
- Lin Liang, Ce Liu, Ying-qing Xu, Baining Guo and Heung-yeung Shum, *Real-time texture synthesis by patch-based sampling*, ACM Transaction on Graphics, Vol. 20, No. 3, July 2001, Pages 127-150  
(Microsoft Paper)

# Basic Idea

**input  
texture**

random placement  
of blocks

neighboring blocks  
constrained by overlap

# Basic Idea

**Image Quilting:** Minimum Error Boundary cut:

minimum error  
boundary cut

**Microsoft Paper:** Image Feathering (blending):

- Be performed along seams
- Makes the sharp changes occurring at the cut line appear more gradual

# Minimum Error Boundary Cut:

$E_{11}$	$E_{12}$	$E_{13}$	$E_{14}$
$E_{21}$	$E_{22}$	$E_{23}$	$E_{24}$

$$e_{22} + \text{Min}\{E_{11}, E_{12}, E_{13}\}$$

$$e_{ij} = (P_{in}(i, j) - P_{Match}(i, j))^2$$

$$E_{ij} = \begin{cases} e_{ij}, & i = 1 \\ e_{ij} + \text{Min}\{E_{i-1, j-1}, E_{i-1, j}, E_{i-1, j+1}\}, & i > 1 \end{cases}$$

Minimum of last row

# Image Feathering:

$$P_{out}(i, j) = \alpha_{ij} P_{in}(i, j) + (1 - \alpha_{ij}) P_{Match}(i, j)$$

- Using  $\alpha_{ij}$  to control the blending effect
- One possible criterion to select  $\alpha_{ij}$  is by their distance to the cutting line

# How to choose the matching patch:

- **Image Quilting:** The most similar patch in the input image, which is defined as:

$$B_{opt} = \arg \min_{B_{in}} \{ dist(\partial B_{in}, \partial B_{out}), B_{in} \in I_{in} \}$$

$\partial B_{in}$  and  $\partial B_{out}$  are the overlapped region in the patch  $B_{in}$  and  $B_{out}$

- **Microsoft Paper:** Randomly select from the set  $S_{Match}$ ; In case  $S_{Match} = \Phi$ , select the most similar patch

$$S_{Match} = \{ B_{in} : dist\{\partial B_{in}, \partial B_{out}\} < d_{max} \}$$

$$d_{max} = \varepsilon \left( \frac{1}{A} \sum_{i,j} (P_{out}(i,j))^2 \right)^{\frac{1}{2}},$$

$P_{in/out}(i,j) \in \partial B_{in/out}$ ,  $A$  is the area of  $\partial B_{in/out}$

# Common Parameters in Both Approaches:

- **Patch size:** Smaller means more matching possibility, yet weaker statistical constraint

From left to right:  $I_{in}$ ,  $I_{out}$  by patch size 16x16, 24x24, 32x32

- **Width of Overlapped Band:** Wider band implies stronger statistical constraints, yet less matching possibilities

# More Parameters in Microsoft Paper:

- Distance tolerance  $d_{\max}$  (Controlled by  $\varepsilon$ ):  
Control the similarity between the synthesis texture and the input texture.

Smaller  $\varepsilon$ : More similarity in local structures;

Greater  $\varepsilon$ : Discontinuous transition between patches

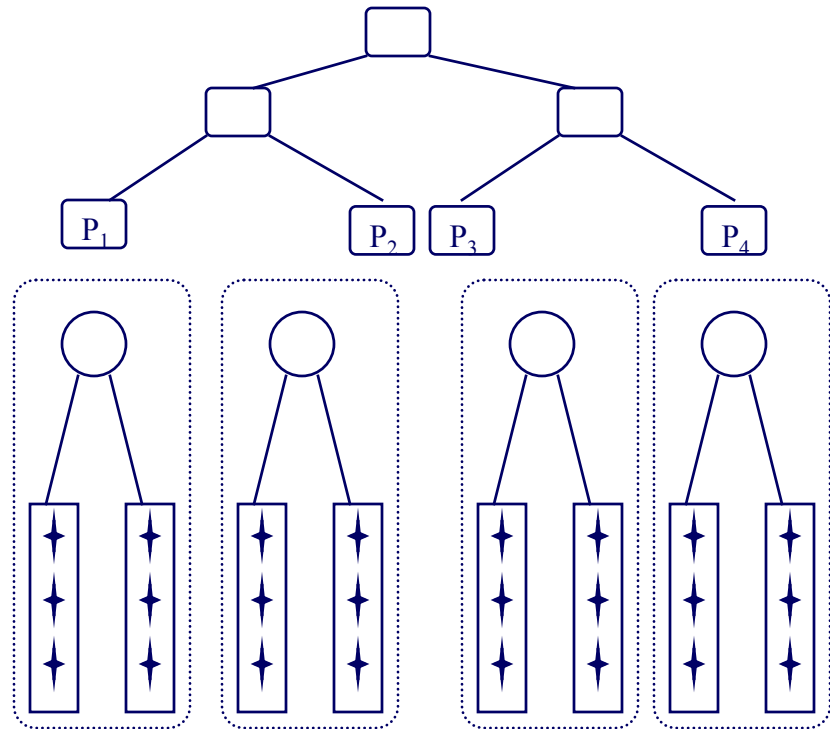

From left to right:  $I_{\text{in}}$ ,  $I_{\text{out}}$  with  $\varepsilon=0, 0.2, 1$  respectively

# Three Steps of Accelerating Technique----

## Step 1:

- Optimized KD-tree for the data-points

# Three Steps of Accelerating Technique----

## Step 1 (Contd.):

- Optimized KD-tree for the data-points
  - Partition the data-space into hypercubes by axis-orthogonal hyperplanes
  - Node: hypercubes enclosing a set of data-points
  - Construction rule: Sliding mid-point rule *V.S.* standard KD-tree splitting rule
    - ★ Both will produce cubes with high-aspect ratio
    - ★ High aspect ratio will increase error
    - ★ Sliding mid-point rule can prevent it from causing problems

# Three Steps of Accelerating Technique----

## Step 2:

- Quadtree Pyramid---Take advantage of image data

- Calculated over  $I_{in}$ ; all other data-points can be extracted from filtered  $I_{in}$ ;
- At every level, four children (higher level images) are computed over images with different shifting along  $x$ - and  $y$ - directions.
- Compare with Gaussian Pyramid: Same: reduce (Smoothing+sub-sampling) and expand (interpolating); different: Gaussian pyramid cannot always find the corresponding pixel in the higher level to the lower level patches

# Three Steps of Accelerating Technique----

## Step 3:

- PCA---Data dimension reduction
  - A lower dimension representation
  - Expanded by the first several eigenvectors of the covariance matrix

Results from Liang's paper

From left the right:

Input sample texture images;

Synthesized texture from  
Liang's approach;

Synthesized texture from  
Efros and Freeman's  
approach

# Texture Transfer

input images

quilting results

# Texture Transfer

- Image quilting is suitable for it : image quilting is based on local image information
- A desired *correspondence map* should be satisfied as well as the texture synthesis requirement.
- *Correspondence map* ( $C(\bullet)$ ):

Spatial Map of some Corresponding Quantity

- Error term is modified to be:

$$\tilde{e}_{ij} = \alpha(P_{in}(i, j) - P_{out}(i, j))^2 + (1 - \alpha)(C(P_{in}(i, j)) - C(P_{out}(i, j)))^2$$

# Results of Image Transfer:

Correspondence map:  
Luminance value

Correspondence map:  
Blurred Luminance value
